1 Final Project - Predicting Movie Genres!

Welcome to the final project of CS109b.

The overall theme of the final project is movie data with a focus on movie genre prediction, because it is an area where we all are more or less application domain experts. First, you will explore your data and the challenges of the problem by exploratory data analysis. Use visualizations to find features that correlate with movie genres. These can be extracted from the movie posters, or meta data, or other data you gather, for example plot summaries or even movie transcripts. You will then compare traditional statistical or machine learning methods like generalized additive models, random forest, Bayesian prediction methods, boosting, and SVM, to deep learning models for movie genre prediction.

For this project you will work in teams of 3-4 people and there are weekly milestones to guide you along the way. Even though the milestones are graded, they are mainly in place to make sure you stay in contact with your TF and make progress with the project. Throughout the project you also have room for creativity and to pursue your own ideas. While you need to hand in the milestones at the appropriate due date, there is nothing preventing you from working on a later milestone ahead of time. We suggest that you read through the whole project and all milestones in the beginning to be able to plan ahead. The project is pretty open ended, so you can be creative and let your data science knowledge shine!

For each milestone you will submit a notebook, in raw (.ipynb) and PDF formats, containing the deliverables of that week and the extra work you did so far. The notebooks need to contain your code, comments, explanations, thoughts, and visualizations. The final deliverables are a two-minute screencast, a report in paper style for a general data science audience, and all your data and code that you developed throughout the project.

Movie genre header

Below is a description of the data and the milestones with their due dates. All work is due by 11:59PM on the due date unless otherwise specified. We expect you to have the mandatory parts finished by the milestone due dates, and there will be no extensions. However, we strongly encourage you to plan ahead. For example, you need to think about the classification task early on to plan how you want to assemble your training data, and it is beneficial to start the deep learning work as early as possible. There is nothing hindering you to already train a model in the EDA phase to get a better feel for what challenges might lay ahead with the data. You should also see the milestone requirements as a basis for your own creativity, and we expect that most of you will go beyond the mandatory deliverables. For example, if you have a great idea about an interesting question that has to do with movie genre, but cannot be answered with the data from TMDb or IMDb, feel free to gather more data from somewhere else.

We provide a data interface in Python, because it is convenient for IMDb, and we will use Python for the deep learning part. Specifically we will use Keras, a deep learning library that provides a high level interface to Google's Tensorflow framework for deep learning. However, if you feel that you prefer to do some of the work, e.g., visualizations or data cleanup, in R then feel free to use it. You can also use Spark to preprocess your data, especially if you collect large amounts of it from other sources.

Important: Your grade for a milestone will depend on the required deliverables you submit at the due date for that milestone. But every milestone, especially the final project submission, can contain additional cool work you did that goes beyond the deliverables spelled out below.

1.0.1 Logistics

Please adhere to the following guidelines for all submissions: - one submission per team - note-books should be submitted as PDF and as raw (.ipynb) version - all notebooks should be executed so they contain relevant visualizations, and other results - try to make it as easy as possible for the TFs to get all relevant information about your work - do not submit big data sets, please provide a readme file with a link instead - the final report should also be submitted as pdf

1.0.2 Movie Data:

The project is based on two different sources of movie data: IMDb and TMDb. TMDb is great, because it provides the movie posters in addition to the metadata. This is crucial for the deep learning part, in which you will try to predict movie genres from posters. IMDb has more metadata available and will supplement the TMDb data you have.

TMDb provides an easy to use API that allows you to download the data selectively. IMDb does not provide an API, but there is a Python interface available to access the metadata. We will use IMDbPY, which is already installed on the AMI and virtual box images for your convenience.

Important: Please remember to limit your data rate when obtaining the data. Play nicely and do not just spam servers as fast as you can. This will prevent your IP from getting banned. The easiest way to do is is to use the sleep function in Python.

1.0.3 Milestone 1: Getting to know your data, due Wednesday, April 5, 2017

In the beginning you should get acquainted with the data sources and do some EDA. Sign up for the TMDb API, and try to download the poster of your favorite movie from within your notebook. Compare the genre entries of IMDb and TMDb for this movie and see if they are the same. Think about and write down some questions that you would like to answer in the following weeks.

Keep the storytelling aspect of your final report in mind and do some pen and paper sketches about the visualizations you would like to produce. Include photographs of those sketches in your notebook.

Most of the time a data scientist spends on a project is spend on cleaning the data. We are lucky that the data we have is already pretty clean. The Python interface to the IMDb ftp files does a lot of the additional work of cleaning as well. However, you will notice that the genre list for each movie from both databases can have different lengths. This needs to be changed in order to train a model to predict the movie genre. It is up to you to think about possible ways to address this problem and to implement one of them. There is no absolute right answer here. It depends on your interests and which questions you have in mind for the project.

Optionally, you could also scrape additional data sources, such as Wikipedia, to obtain plot summaries. That data may give you additional useful features for genera classification.

To guide your decision process, provide at least one visualization of how often genres are mentioned together in pairs. Your visualization should clearly show if a horror romance is more likely to occur in the data than a drama romance.

The notebook to submit for this milestone needs to at least include:

- API code to access the genre and movie poster path of your favorite movie
- Genre for this movie listed by TMDb and IMDb
- A list of the 10 most popular movies of 2016 from TMDb and their genre obtained via the API
- Comments on what challenges you see for predicting movie genre based on the data you have, and how to address them
- Code to generate the movie genre pairs and a suitable visualization of the result
- Additional visualization sketches and EDA with a focus on movie genres
- A list of questions you could answer with this and related data. Get creative here!

The EDA questions do not necessarily have to tie into the modeling part later on. Think freely about things that might be interesting, like which actors are very specific to a genre? Are action movies more prone to producing sequels than romances? However, as you keep the focus on movie genres, think also about correlations you might discover that can help building features from the metadata for prediction. Is the length of a movie title correlated with genre?

1.1 Milestone 1 Submission

1.1.1 CS109b Project - Group 37 (Alexander Dubitskiy, Keenan Venuti, Timur Zambalayev)

Github repository of the project: https://github.com/adubitskiy/cs109b First let's do some initial exploration of the the TMDb and IMDb data.

1.1.2 API code to access the genre and movie poster path of your favorite movie

```
import pandas as pd
        from imdb import IMDb
In [2]: tmdb.API KEY = 'a995a7fe53e021d77d82b99428850ff1'
In [3]: conf = tmdb.Configuration()
        c_info = conf.info()
  Now let's look at the list of the poster sizes from TMDb.
In [4]: img_conf = c_info['images']
        img conf['poster sizes']
Out[4]: [u'w92', u'w154', u'w185', u'w342', u'w500', u'w780', u'original']
  What genres do we have in TMDb? How many?
In [5]: genres = tmdb.Genres().list()
        tmdb_genres = [g['name'] for g in genres['genres'] ]
        print (len (tmdb_genres))
        print (tmdb_genres)
19
[u'Action', u'Adventure', u'Animation', u'Comedy', u'Crime', u'Documentary', u'Drar
  Here's the list of the genres from IMDb (copied from the site). So it's 19 genres in TMDb vs 27
for IMDb.
In [6]: imdb_genres = ['Action','Adventure','Animation','Biography','Comedy','Crime
        print (len (imdb_genres))
        print (imdb_genres)
2.7
['Action', 'Adventure', 'Animation', 'Biography', 'Comedy', 'Crime', 'Documentary',
  Our favorite movie will be "Ghost in the Shell". Let's search for it.
In [7]: search = tmdb.Search()
        response = search.movie(query="ghost in the shell")
        for s in search.results:
            print(s['title'], s['id'], s['release_date'], s['popularity'])
(u'Ghost in the Shell', 315837, u'2017-03-29', 53.86811)
(u'Ghost in the Shell', 9323, u'1995-11-18', 6.135032)
(u'Ghost in the Shell 2.0', 14092, u'2008-07-12', 2.703536)
(u'Ghost in the Shell 2: Innocence', 12140, u'2004-03-06', 2.601958)
(u'Ghost in the Shell Arise - Border 5: Pyrophoric Cult', 381519, u'2015-08-26', 2
```

(u'Ghost in the Shell: The New Movie', 334376, u'2015-06-20', 2.265999)

```
(u'Ghost in the Shell: Stand Alone Complex - Solid State Society', 18874, u'2007-02
(u'Ghost in the Shell: Stand Alone Complex - The Laughing Man', 18839, u'2005-01-03
(u'Ghost In The Shell: The Movie Virtual Reality Diver', 384217, u'2016-02-02', 1.3
(u'Ghost in the Shell Arise - Border 1: Ghost Pain', 196750, u'2013-06-22', 1.46676
(u'Pandora in the Crimson Shell: Ghost Urn', 377885, u'2015-12-05', 1.024687)
(u'Ghost in the Shell Arise - Border 2: Ghost Whispers', 212168, u'2013-11-29', 1.4
(u'Ghost in the Shell Arise - Border 3: Ghost Tears', 240341, u'2014-06-28', 1.5010
(u'Ghost in the Shell Arise - Border 4: Ghost Stands Alone', 279254, u'2014-09-06',
(u'Ghost in the Shell: Stand Alone Complex - Individual Eleven', 111224, u'2006-01-
(u'K\xf4kaku kid\xf4tai Stand Alone Complex - Solid State Society 3D', 446699, u'20
In [8]: tmdb_movie_id = 315837
        tmdb_movie = tmdb.Movies(tmdb_movie_id)
        info = tmdb_movie.info()
        info['title']
Out[8]: u'Ghost in the Shell'
  Its genres from TMDB:
In [9]: for tmdb_genre in info['genres']:
            print tmdb_genre['name']
Action
Drama
Science Fiction
  The movie poster image from TMDB:
In [10]: Image(url= img_conf['base_url'] + img_conf['poster_sizes'][1] + tmdb_movie
Out[10]: <IPython.core.display.Image object>
1.1.3 Genre for this movie listed by TMDb and IMDb
So we found TMDb genres (Action, Drama, Science Fiction) and the poster for our favorite movie.
In [11]: imdb_service = IMDb()
         imdb_movie_id = info['imdb_id'][2:]
         imdb_movie = imdb_service.get_movie(imdb_movie_id)
  The movie genres from IMDB
In [12]: for imdb_genres in imdb_movie.data['genres']:
             print imdb_genres
Action
Crime
Drama
Mystery
Sci-Fi
Thriller
```

1.1.4 A list of the 10 most popular movies of 2016 from TMDb and their genre obtained via the API

IMDB has a comprehensive list of genres, we use IMDB as the main source

return imdb_movie.data['genres']

In [13]: def imdbGenres(imdb_movie):

```
def tmdbGenres(tmdb_movie):
             tmdb_movie_genres = [g['name'] for g in tmdb_movie['genres']]
             tmdb_movie_genres = [g.replace('Science Fiction', 'Sci-Fi') for g in t
             return tmdb_movie_genres
         def combinedGenres(imdb_movie, tmdb_movie):
             return list(set(imdbGenres(imdb_movie)) | set(tmdbGenres(tmdb_movie)))
In [14]: discover = tmdb.Discover()
         disc_result_2016 = discover.movie(query = 'primary_release_year=2016&sort_
  A list of the 10 most popular movies of 2016 from TMDb. We can see differences in IMDB and
TMDB genres.
In [15]: top_movies_2016 = disc_result_2016['results']

1.1.5 Movie genre dataset for exploration

In order to do some of the initial exploration we created movie genre dataset. We used TMDb API to download data for top 11.3k movies. We are building a local IMDB database and we intend to use actors/directors for the further work.

```
start_page = 1
         num_pages = 2 # 1000
         for page in xrange(start_page, num_pages + 1):
             if page != start_page:
                 time.sleep(7)
             elapsed_mins = (time.time() - start_time) / 60.0
             print 'page: %d, elapsed mins: %.2f' % (page, elapsed_mins)
             discover_result = discover.movie(page=page, sort_by='popularity.desc')
             movies = discover_result['results']
             row_list = []
             for movie in movies:
                 movie_id = movie['id']
                 print movie_id, movie['title']
                 try:
                     tmdb_movie = tmdb.Movies(movie_id).info()
                     row_list.append(tmdb_movie)
                 except HTTPError as e:
                     print str(e)
             df = pd.DataFrame(row_list)
             with open('tmdb_movies.csv', 'a') as csv_file:
                 df.to_csv(csv_file, header=False, index=False, encoding='utf-8')
page: 1, elapsed mins: 0.00

```

The first page (top 20 popular movies) is what you can see at this url: https://www.themoviedb.org/movie

We loaded first 11291 movies, then we encountered various problems with the data (movies with no data, repeated instances of the same movies, encoding issues). The load took more than 2 hours. We also had to throttle the load (note using sleep function for 7 seconds). It's because TMDb was limiting the number of requests. We believe it's 40 requests per 10 seconds.

 $Here is the link to this dataset (10Mb): https://github.com/adubitskiy/cs109b/blob/master/Milestone_1/tml. Adubitskiy/cs109b/blob/master/Milestone_1/tml. Adubitskiy$

1.1.6 Comments on what challenges you see for predicting movie genre based on the data you have, and how to address them

One problem that we see with predicting movie genres is that in most cases there are multiple different genres attached to each movie.

- 1) One way to solve this is we can consider one genre at any given moment. For example, we can try to predict for all the movies in the dataset whether they belong to Action genre (yes or no, 1 or 0). We can apply a Logistic regression (for example) and evaluate the accuracy.
- 2) Another possible approach is to consider all possible genre combinations that we see in the dataset. For example, Action + Fantasy + Adventure. We can treat each unique combination as an indidual separate class. One possible problem with this approach is that we could have

a lot of unique genre combinations. A variation of this approach could be considering only pairs or tuples of three of genres.

Using either methodology, we see class imbalance as a future problem and something to account for. We do not want a supervised trained model to over classify a class to get the best accuracy if that accuracy is not real-world applicable.

Sample multi-label model The first approach can be implemented by using OneVsRestClassifier. We use text of the movies overviews to predict the genres and we predict multiple lables per observation.

```
In [17]: from sklearn.feature_extraction.text import CountVectorizer
         from sklearn.preprocessing import MultiLabelBinarizer
         from sklearn.multiclass import OneVsRestClassifier
         from sklearn.svm import LinearSVC
         import nltk.data
         from nltk.corpus import stopwords
         %matplotlib inline
         nltk.download('stopwords')
[nltk_data] Downloading package stopwords to
[nltk_data] C:\Users\Timur\AppData\Roaming\nltk_data...
[nltk_data] Package stopwords is already up-to-date!
Out[17]: True
In [18]: TMDB_MOVIES_COLUMN_NAMES = [
             'adult', 'backdrop_path', 'belongs_to_collection', 'budget', 'genres',
             'original_language', 'original_title', 'overview', 'popularity', 'post
             'production_countries', 'release_date', 'revenue', 'runtime', 'spoken_
             'video', 'vote_average', 'vote_count',
         ]
         def load_tmdb_movies():
             df = pd.read_csv('Milestone_1/tmdb_movies_11291.csv', header=None, nar
             for column_name in ['genres', 'spoken_languages']:
                 df[column_name] = df[column_name].map(lambda d: ast.literal_eval(column_name)
             return df
```

Load movies and prepare the training set by filtering out movies without genres or without reviews

```
In [19]: tmdb_movies_df = load_tmdb_movies()
    has_overview = ~tmdb_movies_df['overview'].isnull()
    has_genre = ~tmdb_movies_df['genres'].apply(lambda x: not x )
    tmdb_movies_with_overview = tmdb_movies_df[has_overview & has_genre]
```

Convert the overviews to a matrix of token counts

```
In [20]: vectorizer = CountVectorizer(
           stop_words = stopwords.words("english"),
           token_pattern = '[a-zA-Z]+[0-9]*',
           max_df = 0.9,
           min_df = 5,
           dtype=np.float32 )
        X = vectorizer.fit_transform(tmdb_movies_with_overview['overview'].values)
        print 'predictor matrix shape:', X.shape
predictor matrix shape: (11022L, 8707L)
In [21]: feature_names = np.array(vectorizer.get_feature_names())
        feature_names
Out[21]: array([u'aaron', u'abandon', u'abandoned', ..., u'zone', u'zoo', u'zooey']
             dtype='<U17')
  Prepare labels for each movie
In [22]: labels = tmdb_movies_with_overview['genres'].apply(lambda x: [g['name'] for
        mlb = MultiLabelBinarizer()
        y = mlb.fit_transform(labels)
        print 'label matrix shape:', y.shape
label matrix shape: (11022L, 20L)
  Fit the classifier and predict using the training set
In [23]: oneVsResClassifier = OneVsRestClassifier(LinearSVC(random_state=0)).fit(X,
        predict = oneVsResClassifier.predict(X)
In [24]: print 'First observation actual label', y[1]
        print 'First observation predicted label: ', predict[1]
        print 'Accuracy on the training set: ', oneVsResClassifier.score(X, y)
Accuracy on the training set: 0.992741789149
```

We cannot comment on the generalization capabilities of the model but the idea of using OneVsRestClassifier seems to be working out fine. We'll explore the idea further in the following milestones probably using different set of features and with proper cross-validation.

1.1.7 Code to generate the movie genre pairs and a suitable visualization of the result

Let's look at the number of genres per movie.

```
In [25]: import ast
         from collections import Counter
         import matplotlib.pyplot as plt
         import numpy as np
         import operator
         import pandas as pd
         import sys
         from IPython.display import display
         TMDB_MOVIES_COLUMN_NAMES = [
             'adult', 'backdrop_path', 'belongs_to_collection', 'budget', 'genres',

total number of movies: 11291
unique values of number of genres per movie: set([0, 1, 2, 3, 4, 5, 6, 7])
mean number of genres per movie: 2.447
```

Our dataset contains top 11,291 TMDb movies by popularity.

We can notice that some movies have zero genres. The mean number of genres per movie is 2.45. The maximum number of genres for one movie is 7.

Let's explore genre counts.

number of unique genres: 20 Drama: 46.5% Comedy: 31.7% Thriller: 25.9% Action: 23.9% Romance: 16.8% Adventure: 14.8% Crime: 13.1% Horror: 12.1% Science Fiction: 10.9% Family: 10.0% Fantasy: 9.0% Animation: 8.0% Mystery: 7.2% History: 3.9%

explore_genre_counts(tmdb_movies_df)

There are 20 unique genres. The most popular is Drama. 46.5% of the movies had Drama as one its genres. The least popular is Foreign (0.5%).

Now we'll look at genre pairs.

War: 3.1%
Music: 2.7%
Western: 2.0%
Documentary: 1.7%
TV Movie: 1.1%
Foreign: 0.5%

Here we have conditional probabilities in rows. For example, if we look at Drama movies, 21.8% of them are also Comedies and 25.1% are Thrillers. In other words: P(Comedy | Drama) = 21.8%.

Let's say that we have a Romance movie. What is more likely for that movie to be a Drama or a Horror movie as well? Our common sense guess will be that Drama is more likely. But how much more likely? $P(Drama \mid Romance) = 67.4\%$, $P(Horror \mid Romance) = 1.6\%$.

```

Component 1

In our datasets current form, we have 5 strong, quantitative predictors: budget, popularity, revenue, runtime, and vote average. We anticipate supplementing these features with external features found from different data sources, but for now, we wanted to visualize how these features map out the movie landscape. By performing a principle component analysis on entire data set and plotting the first two and first 3 PCS (colored by genre), we can see a preliminary distribution as to which genres may be similar (based on clumps) and which movies are themselves similar. The PCA allows us to visualize in 2 and 3 dimensions, the sway of each predictor. However, individual movies share several genres and in this milestone, we have brainstormed ideas as to how to make a single class predictive model. In this plot, the same movie may show up multiple times under different genres.

There are a lot of movies in the dataset and a lot of different genres. Each movie also falls under several genres, making visualization and the creation of a classification model trickier. For a better visual, we isolated the top 5 genres and plotted them.

```
In [39]: def create_dic_and_plot(df, every_genre, ds = ''):
    freq_dic = {}
    for genre in every_genre:
        temp = float(len(df[df['genre_vals'].str.contains(genre)]))/float
        key = genre + ':(' + str(round(temp, 4)*100) + '%)'
        freq_dic[key] = temp
    new = OrderedDict(sorted(freq_dic.items(), key=itemgetter(1)))

plt.bar(range(len(new)), new.values(), align='center', color= 'blue')
    plt.xticks(range(len(new)), new.keys(), rotation=90)
    plt.ylabel('Frequencies')
    plt.xlabel('Genres')
    plt.title('Percentiles of Movies within Each Genre (For all genres with plt.show())
```

Bar plots for genres

```
In [40]: create_dic_and_plot(movie_df112, genre_meta[1], ' for 11.2 dataset')
```

Percentiles of Movies within Each Genre (For all genres within a movie) for 11.2 dataset

We also wanted to understand which genres are most used in classification. From our current dataset, we found Drama to be the most used label, followed by Comedy, Thriller, Action and Romance. Again, at this point in time, each movie has several distinct genre labels, hence the percentages adding to more than 100.

Influential positive and negative terms for different genres

```
In [64]: import ast
    import operator
    import numpy as np
    import pandas as pd
    import matplotlib
    import matplotlib.pyplot as plt
    from sklearn.cross_validation import KFold
    from sklearn.linear_model import LogisticRegression as LogReg
    from sklearn.feature_extraction.text import CountVectorizer
    import nltk.data
    from nltk.corpus import stopwords
    %matplotlib inline
    nltk.download('stopwords')
```

Prints most influential positive and negative terms from the movies overview. Later we could extend this to analyse movies scripts.

1.1.9 A list of questions you could answer with this and related data. Get creative here!

Based on our EDA, we could answer highly predictive questions such as, how much money do you think movie X will make in its box office given input such as genre, cost of production, reviews, review texts, length of film and the rest of our current predictor set. We could generate a confidence interval that estimates upper and lower bounds for box office revenue.

After performing some initial textual analysis on the small description denoting an overview of the movie, we were able to see which genres used which positive and negative words more often. These overviews are relatively small, so using a text as a predictor set may yield little overlap between movie descriptions. However, as this is just an initial analysis, we are able to scale this kind of analysis to entire reviews and possibly even scripts. Because each movie will have a large set of reviews or a long script, we anticipate a classification analysis based on words would be feasible and powerful. Using this line of thinking, we would be able to take in movie reviews and scripts to predict genre and possibly financial data as described previously.

Although we haven't setup an initial model for image classification yet, we see this dataset as a powerful means to understanding more about a movie using just its poster. We showed earlier that we can get movie posters from this dataset. Then, after performing a dimensionality reduction like PCA, we believe a model could be trained to correctly classify movie genres based on their poster alone. We are fortunate that we have an extremely large dataset and poster movies are almost always the same dimensions (no loss in quality for standardizing). We anticipate that these two properties of the dataset will help with the fact that movie posters are incredibly diverse, implying we would need many principle components to capture a significant proportion of the variance among movie posters. From there, a model could take in a movie poster and predict genre.

The most powerful model isn't based on any singular predictor set. Instead, we would consider a methodology that takes in the dataset in full. From there, it is our hope that our models could complement each other where one model is more certain and another is less certain. Given such an extensive dataset and diverse predictors, we anticipate a strong predictive model.
